Pointers in C

BBM 101 - Introduction to Programming I

Hacettepe University Fall 2016

Fuat Akal, Aykut Erdem, Erkut Erdem

Slides based on the material prepared by Carl Burch (Hendrix College) with modifications by Elizabeth Patitsas (U Toronto)

Your First C Program

hello.c

```
/* Welcome to BBM 101 */
#include <stdio.h>
int main(void)
{
    printf("Hello world!\n");
    return 0;
}
```

```
Hello world!
```

Recap: Anatomy of a Typical C Program

```
#preprocessor directives

declarations
  variables
  functions

int main (void){
   declarations;
   statements;
   return value;
}
```

Your First C Program

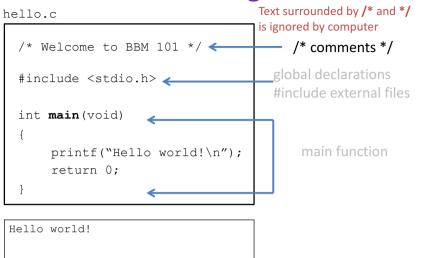

```
/* Welcome to BBM 101 */
#include <stdio.h>

global declarations
#include external files
int main(void)
{
    printf("Hello world!\n");
    return 0;
}
main function
```

Hello world!

hello.c

Your First C Program

```
hello.c

/* Welcome to BBM 101 */

#include <stdio.h>

global declarations
#include external files

int main(void)
{
    printf("Hello world!\n");
    return 0;
}

Hello world!

/* comments */

global declarations
#include external files

"stdio.h" allows standard
input/output operations
main function
```

Your First C Program

```
hello.c

/* Welcome to BBM 101 */
#include <stdio.h>

#include external files

int main(void)
{
    printf("Hello world!\n");
    return 0;
}

Hello world!

Hello world!
/* comments */
global declarations
#include external files

main function
C programs contain one or
more functions, exactly one
of which must be main
```

The main (void) of hello.c

```
int main(void)
{
         printf("Hello world!\n");
         return 0;
}
```

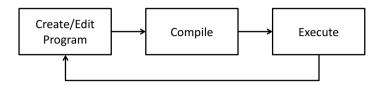

• No arguments.

• Returns an integer variable.

"everything is OK"

Slide credit: Bert Huang

The Programming Process

"The cycle ends once the programmer is satisfied with the program, e.g., performance and correctness-wise."

Identifiers

- A sequence of letters, digits, and the underscore character '_' satisfying
 - identifier = c { c | d }*
 - with c = {'A',..., 'Z', 'a',..., 'z', '_'}, d = {0,...,9}, and asterisk "*" means "0 or more"
- Case-sensitive
 - e.g., firstName and firstname are two different identifiers.
- Identifiers are used for
 - Variable names
 - Function names
 - Macro names

C Statements

- One-line commands
- Always end in semicolon;
- Examples:

```
- call function: printf("hello"); /* from stdio
   */
```

- declare variable: int x;
- assign variable value: x = 123+456;

Identifier Examples

- · Valid identifiers
 - X
 - a1
 - xyz 33
 - integer1
 - Double
- Invalid identifiers
 - xyz.1
- gx^2
- 114West
- int ← This is a keyword
- pi*r*r

Basic Data Types

- Integer (int)
- Character (char)
- Floating Point (float)
- Double Precision Floating Point (double)
- Data Type Modifiers
 - signed / unsigned
 - short / long

Variables Revisited

- What actually happens when we declare variables?
 char a;
- C reserves a byte in memory to store a.
- Where is that memory? At an address.
- Under the hood, C has been keeping track of variables and their addresses.

This week

Pointers

- Pointer Variable Declarations and Initialization
- Pointer Operators
- Pointers to void
- Calling Functions by Reference
- Passing parameters by reference
- sizeof function
- Dynamic Memory Management
- Pointer Arithmetic
- Pointers and Arrays
- Pointers to Functions

Pointers

- We can work with memory addresses too. We can use variables called **pointers**.
- A pointer is a variable that contains the address of a variable.
- Pointers provide a powerful and flexible method for manipulating data in your programs; but they are difficult to master.
- Close relationship with arrays and strings

Slide credit: B. Huang

Benefits of Pointers

- Pointers allow you to reference a large data structure in a compact way.
- Pointers facilitate sharing data between different parts of a program.
 - Call-by-Reference
- **Dynamic memory allocation:** Pointers make it possible to reserve new memory during program execution.

Pointer Variable Declarations and Initialization

- Pointer declarations
 - The syntax for pointer declaration is as follows: type *identifier;

```
e.g. int *myPtr;
```

- Declares a pointer to an int (pointer of type int *)
- Multiple pointers require using a * before each variable declaration

```
int *myPtr1, *myPtr2;
```

- Can declare pointers to any data type
- Initialize pointers to 0, NULL, or an address
 - 0 or NULL points to nothing (NULL preferred)

Pointer Variable Declarations and Initialization

- Pointer variables
 - Contain memory addresses as their values
 - Normal variables contain a specific value (direct reference)

count 7

- Pointers contain address of a variable that has a specific value (indirect reference)
- Indirection referencing a pointer value

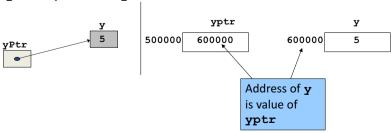

Pointer Operators

- & (address operator)
 - Returns the address of operand

```
int y = 5;
int *yPtr;
yPtr = &y;  // yPtr gets address of y
```

- yPtr "points to" y

Pointer Operators

- * (indirection/dereferencing operator)
 - Returns a synonym/alias of what its operand points to
 - *yptr returns y (because yptr points to y)
 - * can be used for assignment
 - Returns alias to an object*yptr = 7; // changes y to 7
 - Dereferenced pointer (operand of *) must be an *lvalue* (no constants)
- * and & are inverses
 - They cancel each other out

```
/* Using the & and * operators *,
                                The address of a is the value
#include <stdio.h>
                                of aPtr.
int main()
  int a;
                      is an integer */
                                                               The * operator returns an
  int *aPtr;
                    aPtr is a pointer to an integer */
                                                               alias to what its operand
                                                               points to. aPtr points to a,
  a = 7;
                                                               so *aPtr returns a.
                 /* aPtr set to address of a */
  printf( "The address of a is %p\nThe value of aPtr is %p", &a, aPtr );
  printf( "\n\nThe value of a is %d\nThe value of *aPtr is %d", a, *aPtr );
                                                                           Notice how * and &
                                                                           are inverses
  printf( "\n showing that * and & are inverses of
           each other.\n&*aPtr = %p\n*&aPtr = %p\n", &*aPtr, *&aPtr );
  return 0:
                                                                          Program Output
                            The address of a is 0012FF88
                            The value of aPtr is 0012FF88
                            The value of a is 7
                            The value of *aPtr is 7
                            Showing that * and & are inverses of each other.
                            &*aPtr = 0012FF88
                            *&aPtr = 0012FF88
```

```
int rate:
 int *p rate;
 rate = 500;
 p rate = &rate;
          1000
                    1004
                                 1008
                                              1012
             1008
                                      500
 Memory
                                      rate
            p rate
/* Print the values */
printf("rate = %d\n", rate);
                                  /* direct access */
printf("rate = %d\n", *p_rate); /* indirect access */
```

Operator Precedences – Revisited

Operators								Associativity	Туре
()	[]							left to right	highest
+	-	++		!	*	&	(type)	right to left	unary
*	/	%						left to right	multiplicative
+	-							left to right	additive
<	<=	>	>=					left to right	relational
==	!=							left to right	equality
&&								left to right	logical and
П								left to right	logical or
?:								right to left	conditional
=	+=	-=	*=	/=	%=			right to left	assignment
,								left to right	comma

Addressing and Dereferencing

```
int a, b, *p;
a = b = 7;
p = &a;
printf("*p = %d\n", *p);

*p = 3;
printf("a = %d\n", a);

Program Output

p = &b;
    *p = 2 * *p - a;
printf("b = %d \n", b);
*p = 11
```

Addressing and Dereferencing

Declarations and initializations							
int k=3, j=5, *p = &k, *q = &j, *r;							
double x;							
Expression	Equivalent Expression	Value					
p == &k	p == (&k)	1					
p = k + 7	p = (k + 7)	illegal					
* * &p	* (* (&p))	3					
r = &x	r = (& x)	illegal					
7 * * p/ *q +7	(((7 * (*p))) / (*q)) + 7	11					
* (r = &j) *= *p	(* (r = (&j))) *= (*p)	15					

Addressing and Dereferencing

Pointers to void

- void *identifier;
- In C, void represents the absence of type.
- **void** pointers are pointers that point to a value that has no specific type.
- This allows void pointers to point to any data type.
- The data pointed by void pointers cannot be directly dereferenced.
- We have to use explicit type casting before dereferencing it.

Pointers to void

```
int x = 4;
void *q = &x;
int *p = q;
int i = *p;
int j = *(int*)q;
```

Declarations						
int *p;						
float *q;						
void *v;						
Legal assignments	Illegal assignments					
p = 0;	p = 1;					
p = (int *) 1;	v = 1;					
p = v = q;	p = q;					
p = (int *) q;						

Passing parameters by reference

```
void SetToZero (int var)
{
    var = 0;
}
• You would make the following call:
SetToZero(x);
• This function has no effect whatever. Instead, pass a pointer:
void SetToZero (int *ip)
{
    *ip = 0;
}
You would make the following call:
SetToZero(&x);
```

This is referred to as call-by-reference.

Calling Functions by Reference

- Call by reference with pointer arguments
 - Pass address of argument using & operator
 - Allows you to change actual location in memory
 - Arrays are not passed with & because the array name is already a pointer
- * operator
 - Used as alias/nickname for variable inside of function
 void double_it(int *number)
 {
 *number = 2 * (*number);
 }
 - *number used as nickname for the variable passed

```
/* An example using call-by-reference */
#include <stdio.h>

void change_arg(int *y);
int main (void)
{
   int x = 5;
    change_arg(&x);
   printf("%d \n", x);
   return 0;
}

void change_arg(int *y)
{
   *y = *y + 2;
}
```

```
/* Cube a variable using call-by-reference
  with a pointer argument */
                              Notice that the function prototype takes a
                              pointer to an integer (int *).
#include <stdio.h>
                                                 Notice how the address of number is
void cubeByReference( int * ); /* prototype */
                                                 given - cubeByReference expects a
                                                 pointer (an address of a variable).
int main()
   int number = 5;
   printf( "The original value of number is %d", number );
   cubeByReference( &number );
   printf( "\nThe new value of number is %d\n", number );
                                                  Inside cubeByReference, *nPtr is
   return 0;
                                                  used (*nPtr is number).
 void cubeByReference( int *nPtr )
 *nPtr = *nPtr * *nPtr * *nPtr; /* cube number in main */
                                                                   Program Output
           The original value of number is 5
           The new value of number is 125
```

```
/* Swapping arguments (incorrect version) */
#include <stdio.h>

void swap (int p, int q);
int main (void)
{
    int a = 3;
    int b = 7;
    printf("%d %d\n", a,b);
    swap(a,b);
    printf("%d %d\n", a, b);
    return 0;
}

void swap (int p, int q)
{
    int tmp;
    tmp = p;
    p = q;
    q = tmp;
}
```

```
/* Cube a variable using call by value */
#include <stdio.h>
int CubeByValue (int n);
int main(void)
{
    int number = 5;
    printf("The original value of number is %d\n", number);
    number = CubeByValue(number);
    printf("The new value of number is %d\n",number);
    return 0;
}
int CubeByValue (int n)
{
    return (n*n*n);
}
```

```
/* Swapping arguments (correct version) */
#include <stdio.h>
void swap (int *p, int *q);
int main (void)
                                                         q
     int a = 3:
     int b = 7;
     printf("%d %d\n", a,b);
      swap(&a, &b);
     printf("%d %d\n", a, b);
      return 0;
void swap (int *p, int *q)
                                                    7
                                                               3
     int tmp;
      tmp = *p;
      *p = *q;
      *q = tmp;
```

```
* This function separates a number into three parts: a sign (+, -,
* or blank), a whole number magnitude and a fraction part.
* Preconditions: num is defined; signp, wholep and fracp contain
                 addresses of memory cells where results are to be
* Postconditions: function results are stored in cells pointed to by
                  signp, wholep, and fracp
void separate (double num, char *signp, int *wholep, double *fracp)
       double magnitude;
       if (num < 0)
               *signp = '-';
       else if (num == 0)
               *signp = ' ';
               *signp = '+';
       magnitude = fabs(num);
       *wholep = floor(magnitude);
       *fracp = magnitude - *wholep;
```

Bubble Sort Using Call-by-reference

- Implement bubblesort using pointers
 - Swap two elements
 - swap function must receive address (using &) of array elements
 - Array elements have call-by-value default
 - Using pointers and the * operator, swap can switch array elements
- Psuedocode

```
Initialize array
print data in original order
Call function bubblesort
print sorted array
Define bubblesort
```

```
Program Output
                                                     Enter a value to analyze:13.3
                                                     Parts of 13.3000
                                                      sign: +
                                                      whole number magnitude: 13
int main()
                                                     fractional part: 0.3000
        double value;
                                                     Enter a value to analyze: -24.3
        char sn:
                                                     Parts of -24.3000
        int whl;
                                                     whole number magnitude: 24
        double fr:
                                                     fractional part: 0.3000
        /* Gets data */
        printf("Enter a value to analyze:");
        scanf("%lf", &value);
        /* Separates data value in three parts */
        separate(value, &sn, &whl, &fr);
        /* Prints results */
        printf("Parts of %.4f\n sign: %c\n", value, sn);
        printf("whole number magnitude: %d\n", whl);
        printf("fractional part : %.4f\n", fr);
        return 0;
```

```
/* This program puts values into an array, sorts the values into
ascending order, and prints the resulting array. */
#include <stdio.h>
#define SIZE 10

void bubbleSort( int *array, const int size );
void swap( int *element!Ptr, int *element2Ptr );
int main() {
    /* initialize array a */
    int a[ SIZE ] = { 2, 6, 4, 8, 10, 12, 89, 68, 45, 37 };
    int i;
    printf( "Data items in original order\n" );

for ( i = 0; i < SIZE; i++ )
        printf( "%4d", a[ i ] );

bubbleSort( a, SIZE ); /* sort the array */
    printf( "\nData items in ascending order\n" );</pre>
```

sizeof function

- sizeof
 - Returns size of operand in bytes
 - For arrays: size of 1 element * number of elements
 - if sizeof(int) equals 4 bytes, then
 int myArray[10];
 printf("%d", sizeof(myArray));
 will print 40
- sizeof can be used with
 - Variable names
 - Type name
 - Constant values

Example

```
/* swap values at memory locations to which element1Ptr and
    element2Ptr point */
void swap( int *element1Ptr, int *element2Ptr )
{
    int hold = *element1Ptr;
    *element1Ptr = *element2Ptr;
    *element2Ptr = hold;
} /* end function swap */
```

Program Output

```
Data items in original order

2 6 4 8 10 12 89 68 45 37

Data items in ascending order

2 4 6 8 10 12 37 45 68 89
```

```
/* Demonstrating the sizeof operator */
#include <stdio.h>
int main()
                    /* define c */
  char c:
  short s;
                    /* define s */
                    /* define i */
  int i;
  long 1:
                    /* define 1 */
                    /* define f */
  float f:
  double d:
                    /* define d */
  long double ld: /* define ld */
  int array[ 20 ]; /* initialize array */
  int *ptr = array; /* create pointer to array */
```

Example

Program Output

```
sizeof c = 1
                   sizeof(char) = 1
sizeof s = 2
                   sizeof(short) = 2
sizeof i = 4
                   sizeof(int) = 4
sizeof 1 = 4
                   sizeof(long) = 4
sizeof f = 4
                   sizeof(float) = 4
sizeof d = 8
                   sizeof(double) = 8
sizeof 1d = 8
                   sizeof(long double) = 8
sizeof array = 80
sizeof ptr = 4
```

Example

```
printf( "
                sizeof c = %d\tsizeof(char) = %d"
                sizeof s = %d\tsizeof(short) = %d"
        "\n
                sizeof i = %d\tsizeof(int) = %d"
        "\n
                sizeof 1 = %d\tsizeof(long) = %d"
                sizeof f = %d\tsizeof(float) = %d"
                sizeof d = %d\tsizeof(double) = %d"
               sizeof ld = %d\tsizeof(long double) = %d"
        "\n sizeof array = %d"
              sizeof ptr = %d\n",
       sizeof c, sizeof ( char ), sizeof s,
       sizeof( short ), sizeof i, sizeof( int ),
       sizeof 1, sizeof(long), sizeof f,
       sizeof( float ), sizeof d, sizeof( double ),
       sizeof ld, sizeof( long double ),
       sizeof array, sizeof ptr );
return 0;
```

Dynamic Memory Management

- **Static memory allocation:** space for the object is provided in the binary at <u>compile-time</u>
- **Dynamic memory allocation:** blocks of memory of arbitrary size can be requested at <u>run-time</u>
- The four dynamic memory management functions are malloc, calloc, realloc, and free.
- These functions are included in the header file <stdlib.h>.

Dynamic Memory Management

- void *malloc(size t size);
- allocates storage for an object whose size is specified by size:
 - It returns a pointer to the allocated storage,
 - **NULL** if it is not possible to allocate the storage requested.
 - The allocated storage is not initialized in any way.
- e.g. float *fp, fa[10];
 fp = (float *) malloc(sizeof(fa));
 allocates the storage to hold an array of 10 floating-point elements, and assigns the pointer to this storage to fp.

Dynamic Memory Management

- void *realloc(void *p, size_t size);
- changes the size of the object pointed to by **p** to **size**.
 - It returns a pointer to the new storage,
 - NULL if it is not possible to resize the object, in which case the object (*p) remains unchanged.
 - The new size may be larger (the original contents are preserved and the remaining space is unitialized) or smaller (the contents are unchanged upto the new size) than the original size.

Dynamic Memory Management

- void *calloc(size t nobj, size t size);
- allocates the storage for an array of nobj objects, each of size
 size.
 - It returns a pointer to the allocated storage,
 - **NULL** if it is not possible to allocate the storage requested.
 - The allocated storage is initialized to zeros.
- e.g. double *dp, da[10];
 dp=(double *) calloc(10, sizeof(double));
 allocates the storage to hold an array of 10 double values,
 and assigns the pointer to this storage to dp.

Dynamic Memory Management

```
• e.g. char *cp;
      cp =(char *) malloc(sizeof("computer"));
      strcpy(cp, "computer");
cp points to an array of 9 characters containing the null-terminated string computer.

cp = (char *) realloc(cp, sizeof("compute"));
discards the trailing '\0' and makes cp point to an array if 8 characters containing the characters in computer

cp=(char *) realloc(cp, sizeof("computerization"));
cp points to an array of 16 characters, the first 9 of which contain the null-terminated string computer and the remaining 7 are uninitialized.
```

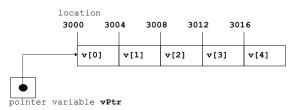

Dynamic Memory Management

- void *free(void *p);
- deallocates the storage pointed to by p, where p is a pointer to the storage previously allocated by malloc, calloc, or realloc.

```
e.g. free(fp);free(dp);free(cp);
```

Pointer Expressions and Pointer Arithmetic

- 5 element int array on machine with 4 byte ints
 - vPtr points to first element v[0]
 - i.e. location 3000 (vPtr = 3000)
 - vPtr += 2; sets vPtr to 3008
 - **vPtr** points to **v**[2] (incremented by 2), but the machine has 4 byte **ints**, so it points to address 3008

Pointer Arithmetic

- Arithmetic operations can be performed on pointers
 - Increment/decrement pointer (++ or --)
 - Add an integer to a pointer(+ or += , or -=)
 - Pointers may be subtracted from each other
 - Operations meaningless unless performed on an array

Pointer Expressions and Pointer Arithmetic

- Subtracting pointers
 - Returns number of elements from one to the other. If ${\tt vPtr} = {\tt \&v[0]};$
 - vPtr2 = &v[2]; //vPtr2 = vPtr + 2;
 vPtr2 vPtr would produce 2
- Pointer comparison (<, == , >)
 - See which pointer points to the higher numbered array element
 - Also, see if a pointer points to 0

Pointer Expressions and Pointer Arithmetic

- Pointers of the same type can be assigned to each other
 - If not the same type, a cast operator must be used
 - Exception: pointer to void (type void *)
 - Generic pointer, represents any type
 - No casting needed to convert a pointer to void pointer
 - void pointers cannot be dereferenced

Example

```
int SumIntegerArray(int *ip, int n)
{
   int i, sum;
   sum = 0;
   for (i=0; i < n; i++) {
      sum += *ip++;
   }
   return sum;
}
Assume
  int sum, list[5];
are declared in the main function. We can make the following function call:
sum = SumIntegerArray(list, 5);</pre>
```

Pointers

```
300
int a=10;
                                  address
                     var. name
int *b;
                                   1200
                                              1200 8
int **c;
                                   1300
int d[3]={1,2,3};
                                   1400
                                             1300 1500 -
                                   1500
                                              1400 1300
b=&a:
*b=5:
                                              1500 9
c=&b;
                                             1504 2
*(*c)=8;
                                             1508 15
b=d:
*(*c)=9;
*(*c+2)=15;
```

```
#include<stdio.h>
#include<stdlib.h>

int main(void) {
   int *array, *p;
   int i,no_elements;
   printf("Enter number of elements: ");
   scanf("%d",&no_elements);

printf("Enter the elements: ");
   array = ( int* )malloc( no_elements*sizeof( int ) );
   for(p=array,i=0; i<no_elements; i++, p++)
        scanf("%d",p);

printf("Elements: ");
   for(p=array,i=0; i<no_elements; i++, p++)
        printf("%d ",*p);
   printf("\n");</pre>
```

```
array = ( int* )realloc(array, (no elements+2)*sizeof( int ) );
printf("Enter two new elements: ");
for(p=array,i=0; i<no elements; i++, p++);</pre>
for(; i<no elements+2; i++, p++)</pre>
     scanf("%d",p);
printf("Elements: ");
for(p=array,i=0; i<no elements+2; i++, p++)</pre>
    printf("%d ",*p);
printf("\n");
free (array):
                                               Program Output
return 0;
                            Enter number of elements: 4
                            Enter the elements: 2 3 4 5
                            Elements: 2 3 4 5
                            Enter two new elements: 6 7
                            Elements: 2 3 4 5 6 7
```

Example

```
/* Converting lowercase letters to uppercase letters using a non-constant
    pointer to non-constant data */
#include <stdio.h>
#include <ctype.h>

void convertToUppercase( char *sPtr );
int main()
{
    char string[] = "characters and $32.98"; /* initialize char array */
    printf( "The string before conversion is: %s", string );
    convertToUppercase( string );
    printf( "\nThe string after conversion is: %s\n", string );
    return 0; /* indicates successful termination */
}
```

Using the const Qualifier with Pointers**

- const qualifier
 - Variable cannot be changed
 - Use **const** if function does not need to change a variable
 - Attempting to change a const variable produces an error
- const pointers
 - Point to a constant memory location
 - Must be initialized when defined
 - int *const myPtr = &x;
 - Type int *const constant pointer to an int
 - const int *myPtr = &x;
 - Regular pointer to a const int
 - const int *const Ptr = &x;
 - · const pointer to a const int
 - x can be changed, but not *Ptr

Example

Program Output

The string before conversion is: characters and \$32.98 The string after conversion is: CHARACTERS AND \$32.98

```
/* Printing a string one character at a time using a non-constant pointer
    to constant data */

#include <stdio.h>

void printCharacters( const char *sPtr );

int main()
{
    /* initialize char array */
    char string[] = "print characters of a string";

    printf( "The string is:\n" );
    printCharacters( string );
    printf( "\n" );

    return 0;
}
```

Example

Example

```
/* sPtr cannot modify the character to which it points, i.e.,
    sPtr is a "read-only" pointer */

void printCharacters( const char *sPtr )
{
    /* loop through entire string */
    for (; *sPtr != '\0'; sPtr++ )
        printf( "%c", *sPtr );
} /* end function printCharacters */
```

Program Output

```
The string is: print characters of a string
```

```
/* Attempting to modify a constant pointer to non-constant data */
#include <stdio.h>

int main()
{
    int x; /* define x */
    int y; /* define y */
    Changing *ptr is allowed - x is
    not a constant.
    /* ptr is a constant pointer to ar
    through ptr, but ptr always points to the same memory location */
    int * const ptr = &x;

    *ptr = 7 /* allowed: *ptr is not const */
    ptr = &y; /* error: ptr is const; cannot assign new address */
    return 0;
} /* end main */

Syntax error: l-value specifies const object
```

```
/* Attempting to modify a constant pointer to constant data. */
#include <stdio.h>

int main() {
    int x = 5; /* initialize x */
    int y; /* define y */

    /* ptr is a constant pointer to a constant integer. ptr always points to
        the same location; the integer at that location cannot be modified */
    const int *const ptr = &x;
    printf( "%d\n", *ptr );

    *ptr = 7; /* error: *ptr is const; cannot assign new value */
    ptr = &y; /* error: ptr is const; cannot assign new address */

    return 0; /* indicates successful termination */
} /* end main */

    Syntax error: assignment of read-only location syntax error: assignment of read-only variable 'ptr'
```

The Relationship between Pointers and Arrays

- Arrays and pointers are closely related
 - Array name is like a constant pointer
 - Pointers can do array subscripting operations
- Declare an array b[5] and a pointer bPtr
 - To set them equal to one another use:

```
bPtr = b;
```

 The array name (b) is actually the address of first element of the array b[5]

```
bPtr = \&b[0]
```

• Explicitly assigns bPtr to address of first element of b

Pointers and Arrays

- Arrays are implemented as pointers.
- Consider:

```
double list[3];
&list[1] : is the address of the second element
&list[i] : the address of list[i] which is
   calculated by the formula
        base address of the array + i * 8
```

The Relationship between Pointers and Arrays

```
- Element b[3]
```

- Can be accessed by * (bPtr+3)
 - Where **n** is the offset. Called pointer/offset notation
- Can be accessed by bptr[3]
 - Called pointer/subscript notation
 - **bPtr**[3] same as **b**[3]
- Can be accessed by performing pointer arithmetic on the array itself

```
* (b+3)
```

Example (cont.)

```
/* Using subscripting and pointer notations with arrays */
#include <stdio.h>
int main(void)
{
   int i, offset, b[4]={10,20,30,40};
   int *bPtr = b;

/* Array is printed with array subscript notation */
   for (i=0; i < 4; i++)
        printf("b[%d] = %d\n", i, b[i]);</pre>
```

Example (cont.)

```
b[0] = 10
b[1] = 20
b[2] = 30
b[ 3 ] = 40
(b + 0) = 10
*(b+1)=20
*(b+2)=30
*(b+3)=40
bPtr[ 0 ] = 10
bPtr[1] = 20
bPtr[2] = 30
bPtr[3] = 40
*(bPtr + 0) = 10
*(bPtr + 1) = 20
*(bPtr + 2) = 30
*(bPtr + 3) = 40
```

Example (cont.)

```
/* Copying a string using array notation and pointer notation. */
#include <stdio.h>
void copy1( char *s1, const char *s2 );
void copy2( char *s1, const char *s2 );
int main()
 char string1[ 10 ];
                              /* create array string1 */
 char *string2 = "Hello";
                              /* create a pointer to a string */
 char string3[ 10 ];
                              /* create array string3 */
 char string4[] = "Good Bye"; /* create a pointer to a string */
 copy1( string1, string2 );
 printf( "string1 = %s\n", string1 );
 copy2( string3, string4 );
 printf( "string3 = %s\n", string3 );
 return 0;
```

```
/* copy s2 to s1 using array notation */
void copy1( char *s1, const char *s2 )
{
    int i;
    for ( i = 0; ( s1[ i ] = s2[ i ] ) != '\0'; i++ )
        ;
} /* end function copy1 */

/* copy s2 to s1 using pointer notation */
void copy2( char *s1, const char *s2 )
{
    /* loop through strings */
    for (; ( *s1 = *s2 ) != '\0'; s1++, s2++ )
        ;
} /* end function copy2 */
```

Program Output

```
string1 = Hello
string3 = Good Bye
```

Pointers to Functions

- Pointer to function
 - Contains address of function
 - Similar to how array name is address of first element
 - Function name is starting address of code that defines function
- Function pointers can be
 - Passed to functions
 - Stored in arrays
 - Assigned to other function pointers

Arrays of Pointers

- Arrays can contain pointers
- · For example: an array of strings

- Strings are pointers to the first character
- char * each element of suit is a pointer to a char
- The strings are not actually stored in the array suit, only pointers to the strings are stored

suit array has a fixed size, but strings can be of any size

Pointers to Functions

- Example: bubblesort
 - Function bubble takes a function pointer
 - bubble calls this helper function
 - · this determines ascending or descending sorting
 - The argument in **bubblesort** for the function pointer:

```
int ( *compare ) ( int a, int b )
```

tells bubblesort to expect a pointer to a function that takes two ints and returns an int

– If the parentheses were left out:

```
int *compare( int a, int b )
```

 Defines a function that receives two integers and returns a pointer to a int.

Example

```
/* multipurpose bubble sort; parameter compare is a pointer to
   the comparison function that determines sorting order */
void bubble( int work[], const int size, int (*compare)( int a, int b ) )
{
   int pass;    /* pass counter */
   int count;    /* comparison counter */

   void swap( int *elementlPtr, int *element2ptr );
   for ( pass = 1; pass < size; pass++ ) {
      for ( count = 0; count < size - 1; count++ ) {
            /* if adjacent elements are out of order, swap them */
            if ( (*compare) ( work[ count ], work[ count + 1 ] ) ) {
                 swap( &work[ count ], &work[ count + 1 ] );
            }
        }
    }
} /* end function bubble */</pre>
```

Example

```
/* output original array */
   for ( counter = 0; counter < SIZE; counter++ )
        printf( "%5d", a[ counter ] );
/* sort array in ascending order; pass function ascending as an argument */
   if ( order == 1 ) {
        bubble( a, SIZE, ascending );
        printf( "\nData items in ascending order\n" ); }
   else { /* pass function descending */
        bubble( a, SIZE, descending );
        printf( "\nData items in descending order\n" ); }
/* output sorted array */
   for ( counter = 0; counter < SIZE; counter++ )
        printf( "%5d", a[ counter ] );
   printf( "\n" );
   return 0;
}</pre>
```

```
/*swap values at memory locations to which element1Ptr and element2Ptr point */
    void swap( int *element1Ptr, int *element2Ptr )
    {
        int hold; /* temporary holding variable */
        hold = *element1Ptr;
        *element1Ptr = *element2Ptr;
        *element2Ptr = hold;
    } /* end function swap */

/* determine whether elements are out of order for an ascending order sort */
    int ascending( int a, int b ) {
        return b < a;
    } /* end function ascending */

/* determine whether elements are out of order for a descending order sort */
    int descending( int a, int b ) {
        return b > a; /* swap if b is greater than a */
    } /* end function descending */
```

Program Output
